AD822ANZ

Analog Devices

Precision Amplifiers SGL-Supply RR Lo Pwr FET-Inpt Dual

Any questions, please feel free to contact us.
info@kaimte.com

FEATURES

True single-supply operation

Output swings rail-to-rail

Input voltage range extends below ground

Single-supply capability from 5 V to 30 V

Dual-supply capability from ± 2.5 V to ± 15 V

High load drive

Capacitive load drive of 350 pF, $G = +1$

Minimum output current of 15 mA

Excellent ac performance for low power

800 μ A maximum quiescent current per amplifier

Unity-gain bandwidth: 1.8 MHz

Slew rate of 3 V/ μ s

Good dc performance

800 μ V maximum input offset voltage

2 μ V/ $^{\circ}$ C typical offset voltage drift

25 pA maximum input bias current

Low noise

13 nV/ $\sqrt{\text{Hz}}$ at 10 kHz

No phase inversion

APPLICATIONS

Battery-powered precision instrumentation

Photodiode preamps

Active filters

12-bit to 14-bit data acquisition systems

Medical instrumentation

Low power references and regulators

GENERAL DESCRIPTION

The AD822 is a dual precision, low power FET input op amp that can operate from a single supply of 5 V to 30 V or from dual supplies of ± 2.5 V to ± 15 V. It has true single-supply capability with an input voltage range extending below the negative rail, allowing the AD822 to accommodate input signals below ground while in the single-supply mode. Output voltage swing extends to within 10 mV of each rail, providing the maximum output dynamic range.

Offset voltage of 800 μ V maximum, offset voltage drift of 2 μ V/ $^{\circ}$ C, input bias currents below 25 pA, and low input voltage noise provide dc precision with source impedances up to a gigaohm. The 1.8 MHz unity-gain bandwidth, -93 dB total harmonic distortion (THD) at 10 kHz, and 3 V/ μ s slew rate are provided with a low supply current of 800 μ A per amplifier.

7/93—Revision 0: Initial Version

The AD822 drives up to 350 pF of direct capacitive load as a follower and provides a minimum output current of 15 mA. This allows the amplifier to handle a wide range of load conditions. Its combination of ac and dc performance, plus the outstanding load drive capability, results in an exceptionally versatile amplifier for the single-supply user.

The AD822 is available in two performance grades. The A grade and B grade are rated over the industrial temperature range of -40°C to $+85^{\circ}\text{C}$.

The AD822 is offered in three varieties of 8-lead packages: PDIP, MSOP, and SOIC_N.

Figure 3. Gain of 2 Amplifier; $V_S = 5\text{ V}$, 0 V ,
 $V_{IN} = 2.5\text{ V}$ Sine Centered at 1.25 V , $R_L = 100\ \Omega$

SPECIFICATIONS

$V_S = 0\text{ V}, 5\text{ V}$ at $T_A = 25^\circ\text{C}$, $V_{CM} = 0\text{ V}$, $V_{OUT} = 0.2\text{ V}$, unless otherwise noted.

¹ This is a functional specification. Amplifier bandwidth decreases when the input common-mode voltage is driven in the range (V₊ - 1 V) to V₊. Common-mode error voltage is typically less than 5 mV with the common-mode voltage set at 1 V below the positive supply.

² V_{OL} - V_{EE} is defined as the difference between the lowest possible output voltage (V_{OL}) and the negative voltage supply rail (V_{EE}). V_{CC} - V_{OH} is defined as the difference between the highest possible output voltage (V_{OH}) and the positive supply voltage (V_{CC}).

$V_S = \pm 5\text{ V}$ at $T_A = 25^\circ\text{C}$, $V_{CM} = 0\text{ V}$, $V_{OUT} = 0\text{ V}$, unless otherwise noted.

² $V_{OL} - V_{EE}$ is defined as the difference between the lowest possible output voltage (V_{OL}) and the negative voltage supply rail (V_{EE}). $V_{CC} - V_{OH}$ is defined as the difference between the highest possible output voltage (V_{OH}) and the positive supply voltage (V_{CC}).

ABSOLUTE MAXIMUM RATINGS

Table 4.

Parameter	Rating
Supply Voltage	±18 V
Internal Power Dissipation	
8-Lead PDIP (N)	Observe derating curves
8-Lead SOIC_N (R)	Observe derating curves
8-Lead MSOP (RM)	Observe derating curves
Input Voltage ¹	((V+) + 0.2 V) to ((V-) - 20 V)
Output Short-Circuit Duration	Indefinite
Differential Input Voltage	±30 V
Storage Temperature Range (N)	-65°C to +125°C
Storage Temperature Range (R, RM)	-65°C to +150°C
Operating Temperature Range	
A Grade and B Grade	-40°C to +85°C
Lead Temperature (Soldering, 60 sec)	260°C

¹ See the Input Characteristics section.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 5. Thermal Resistance

Package Type	θ_{JA}	Unit
8-lead PDIP (N)	90	°C/W
8-lead SOIC_N (R)	160	°C/W
8-lead MSOP (RM)	190	°C/W

MAXIMUM POWER DISSIPATION

The maximum power that can be safely dissipated by the AD822 is limited by the associated rise in junction temperature. For plastic packages, the maximum safe junction temperature is 145°C. If these maximums are exceeded momentarily, proper circuit operation is restored as soon as the die temperature is reduced. Leaving the device in the overheated condition for an extended period can result in device burnout. To ensure proper operation, it is important to observe the derating curves shown in Figure 27.

While the AD822 is internally short-circuit protected, this may not be sufficient to guarantee that the maximum junction temperature is not exceeded under all conditions. With power supplies ±12 V or less at an ambient temperature of 25°C or less, if the output node is shorted to a supply rail, then the amplifier is not destroyed, even if this condition persists for an extended period.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

APPLICATIONS INFORMATION

INPUT CHARACTERISTICS

In the [AD822](#), N-channel JFETs are used to provide a low offset, low noise, high impedance input stage. Minimum input common-mode voltage extends from 0.2 V below $-V_S$ to 1 V less than $+V_S$. Driving the input voltage closer to the positive rail causes a loss of amplifier bandwidth (as can be seen by comparing the large signal responses shown in Figure 34 and Figure 37) and increased common-mode voltage error as illustrated in Figure 20.

The [AD822](#) does not exhibit phase reversal for input voltages up to and including $+V_S$. Figure 42 shows the response of an [AD822](#) voltage follower to a 0 V to 5 V ($+V_S$) square wave input. The input and output are superimposed. The output tracks the input up to $+V_S$ without phase reversal. The reduced bandwidth above a 4 V input causes the rounding of the output waveform. For input voltages greater than $+V_S$, a resistor in series with the [AD822](#) noninverting input prevents phase reversal, at the expense of greater input voltage noise. This is illustrated in Figure 42.

Because the input stage uses N-channel JFETs, input current during normal operation is negative; the current flows out from the input terminals. If the input voltage is driven more positive than $+V_S - 0.4$ V, then the input current reverses direction as internal device junctions become forward biased. This is illustrated in Figure 7.

A current-limiting resistor should be used in series with the input of the [AD822](#) if there is a possibility of the input voltage exceeding the positive supply by more than 300 mV, or if an input voltage is applied to the [AD822](#) when $+V_S$ or $-V_S = 0$ V. The amplifier is damaged if left in that condition for more than 10 seconds. A 1 k Ω resistor allows the amplifier to withstand up to 10 V of continuous overvoltage and increases the input voltage noise by a negligible amount.

Input voltages less than $-V_S$ are different. The amplifier can safely withstand input voltages 20 V below the negative supply voltage if the total voltage from the positive supply to the input terminal is less than 36 V. In addition, the input stage typically maintains picoampere (pA) level input currents across that input voltage range.

The [AD822](#) is designed for 13 nV/ $\sqrt{\text{Hz}}$ wideband input voltage noise and maintains low noise performance to low frequencies (refer to Figure 14). This noise performance, along with the [AD822](#) low input current and current noise, means that the [AD822](#) contributes negligible noise for applications with source resistances greater than 10 k Ω and signal bandwidths greater than 1 kHz. This is illustrated in Figure 43.

Figure 43. Total Noise vs. Source Impedance

OUTPUT CHARACTERISTICS

The [AD822](#) unique bipolar rail-to-rail output stage swings within 5 mV of the negative supply and 10 mV of the positive supply with no external resistive load. The approximate output saturation resistance of the [AD822](#) is 40 Ω sourcing and 20 Ω sinking, which can be used to estimate output saturation voltage when driving heavier current loads. For instance, when sourcing 5 mA, the saturation voltage to the positive supply rail is 200 mV; when sinking 5 mA, the saturation voltage to the negative rail is 100 mV.

The open-loop gain characteristic of the amplifier changes as a function of resistive load, as shown in Figure 10 to Figure 13. For load resistances over 20 k Ω , the [AD822](#) input error voltage is virtually unchanged until the output voltage is driven to 180 mV of either supply.

If the [AD822](#) output is overdriven so that either of the output devices are saturated, the amplifier recovers within 2 μs of the input returning to the linear operating region of the amplifier.

Direct capacitive loads interact with the effective output impedance of the amplifier to form an additional pole in the amplifier feedback loop, which can cause excessive peaking on the pulse response or loss of stability. The worst case occurs when the amplifier is used as a unity-gain follower. Figure 44 shows the [AD822](#) pulse response as a unity-gain follower driving 350 pF. This amount of overshoot indicates approximately 20° of phase margin—the system is stable, but nearing the edge. Configurations with less loop gain, and as a result less loop bandwidth, are much less sensitive to capacitance load effects.

Figure 44. Small Signal Response of AD822 as Unity-Gain Follower Driving 350 pF

Figure 45 is a plot of noise gain vs. capacitive load that results in a 20° phase margin for the AD822. Noise gain is the inverse of the feedback attenuation factor provided by the feedback network in use.

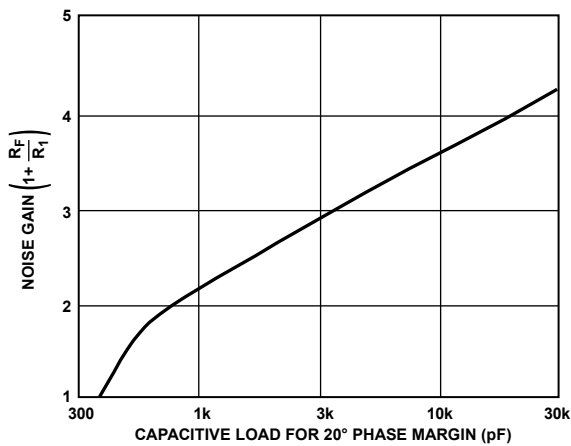

Figure 45. Noise Gain vs. Capacitive Load Tolerance

Figure 46 shows a method for extending capacitance load drive capability for a unity-gain follower. With these component values, the circuit drives 5000 pF with a 10% overshoot.

Figure 46. Extending Unity-Gain Follower Capacitive Load Capability Beyond 350 pF

SINGLE-SUPPLY VOLTAGE TO FREQUENCY CONVERTER

The circuit shown in Figure 47 uses the AD822 to drive a low power timer that produces a stable pulse of width t_1 . The positive going output pulse is integrated by R1 and C1 and used as one input to the AD822 that is connected as a differential integrator. The other input (nonloading) is the unknown voltage, V_{IN} . The AD822 output drives the timer trigger input, closing the overall feedback loop.

Figure 47. Single-Supply Voltage to Frequency Converter

Typical AD822 bias currents of 2 pA allow MΩ range source impedances with negligible dc errors. Linearity errors on the order of 0.01% full scale can be achieved with this circuit. This performance is obtained with a 5 V single supply that delivers less than 1 mA to the entire circuit.

SINGLE-SUPPLY PROGRAMMABLE GAIN INSTRUMENTATION AMPLIFIER

The AD822 can be configured as a single-supply instrumentation amplifier that is able to operate from single supplies down to 3 V or dual supplies up to ±15 V. Using only one AD822 rather than three separate op amps, this circuit is cost and power efficient. The 2 pA bias currents of the AD822 FET inputs minimize offset errors caused by high, unbalanced source impedances.

An array of precision thin film resistors sets the in-amp gain to be either 10 or 100. These resistors are laser trimmed to ratio match to 0.01% and have a maximum differential temperature coefficient of 5 ppm/°C.

Table 6. In-Amp Performance

Parameters	V _S = 3 V, 0 V	V _S = ±5 V
CMRR	74 dB	80 dB
Common-Mode Voltage Range	-0.2 V to +2 V	-5.2 V to +4 V
3 dB BW		
G = 10	180 kHz	180 kHz
G = 100	18 kHz	18 kHz
t _{SETTLING}		
2 V Step	2 μs	
5 V Step		5 μs
Noise @ f = 1 kHz		
G = 10	270 nV/√Hz	270 nV/√Hz
G = 100	2.2 μV/√Hz	2.2 μV/√Hz
I _{SUPPLY} (Total)	1.10 mA	1.15 mA

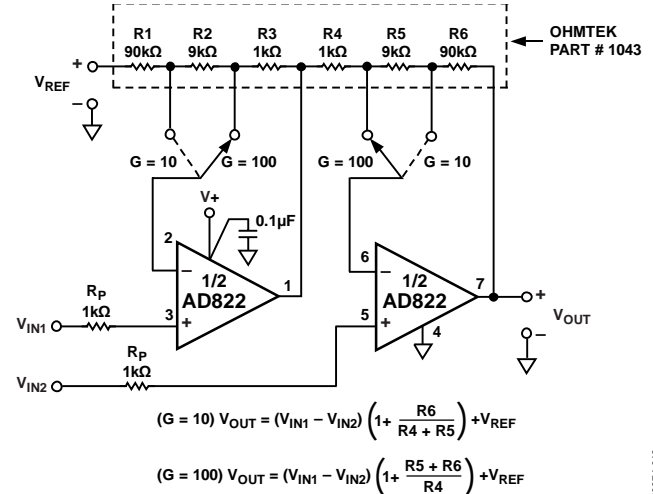

Figure 49. A Single-Supply Programmable Instrumentation Amplifier

LOW DROPOUT BIPOLAR BRIDGE DRIVER

The AD822 can be used for driving a 350 Ω Wheatstone bridge. Figure 50 shows one half of the AD822 being used to buffer the AD589, a 1.235 V low power reference. The output of 4.5 V can be used to drive an analog-to-digital converter (ADC) front end. The other half of the AD822 is configured as a unity-gain inverter and generates the other bridge input of -4.5 V. Resistor R1 and Resistor R2 provide a constant current for bridge excitation. The AD620 low power instrumentation amplifier is used to condition the differential output voltage of the bridge. The gain of the AD620 is programmed using an external resistor (R_G) and determined by

$$G = \frac{49.9 \text{ k}\Omega}{R_G} + 1$$
